## 1 Tasks

For each data set, we assume the number of cluster is known and denoted by  $c$ . You are required to implement the following clustering algorithms:

- the standard k-medoids algorithm in Section 6.3.4 of the textbook [1], and you need to use  $\ell_1$ -norm to calculate the distance between two instances, e.g., the  $\ell_1$ -norm distance of  $X_i$  and  $X_j$  is:

$$Dist(X_i, X_j) = \|X_i - X_j\|_1 = \sum_{k=1}^d |x_{ik} - x_{jk}|, \quad (1)$$

the  $x_{ik}$  is the  $k$  feature of the instance  $X_i$ .

- The spectral clustering algorithm in [2,3]. To make life easier, you can follow Step 1(b), Step 2(b) and Step 3 in [2], where  $m = c$  in Step 3. After that, you will get a  $c$ -dimensional representant for each data point, and then apply k-medoids you realized before to clustering the new data. Again, you set  $k = c$  in k-medoids.
  - There is a parameter in Step 1(b), which is the number of nearest neighbors  $n$ . You can try  $n = 3, 6$  and  $9$ .

Note that optimization algorithms for k-medoids can only find local optimum. So, each time you solve k-medoids, you need to run its optimization algorithm at least 10 times with different initializations, and use the solution with smallest objective value. To compare different methods quantitatively, you are required to calculate the Purity and Gini index of Section 6.9.2 of the textbook [1]. In the report, you may present the final results as follows:

	k-medoids	Spectral(n=3)	Spectral(n=6)	Spectral(n=9)
Dataset1				
Dataset2				
...				

Table 1: Purity of different algorithms

	k-medoids	Spectral(n=3)	Spectral(n=6)	Spectral(n=9)
Dataset1				
Dataset2				
...				

Table 2: Gini index of different algorithms
